ABSTRACT: Objective: To formulate economic transdermal patch of lornoxicam (LX) and to study its anti-inflammatory activity on acute and chronic inflammatory in rat models. Method: Three LX transdermal patches (F1, F2, and F3) consist of Eudragit RL-100, and RS-100 in three different ratios (1:2, 1:1 and 2:1) were prepared respectively by the solvent evaporation technique. All formulations contain diethyl phthalate as a plasticizer. The physicochemical compatibility of the drug and the polymers was studied by differential scanning calorimetry. The prepared LX transdermal patches were evaluated for their drug content, patch thickness, folding endurance, surface pH, and in vitro drug permeation. The anti-inflammatory activity of LX transdermal patch was determined using two experimental animal designs, one for acute inflammation (rat paw edema) and the other for chronic inflammation (granuloma pouch) on eighty adult albino rats. The results obtained were statistically analyzed. Results: The data showed physicochemical compatibility between the drug and the polymers used. The LX patches (F1, F2, and F3) prepared were uniform thickness, drug content, and the pH of the LX patch was found to be 6.5. Increasing the ratio of the Eudragit® RL-100 polymer to eudragit RS 100 (F3) showed a corresponding increase in the folding endurance of patches. Diethyl phthalate led to increasing elasticity for the patches. F3 showed higher drug permeation than F2 and F1. Edema (anti-inflammatory effect) was significantly decreased in group V followed by group IV then by group III in case of the two animal experimental designs. Group V received LX transdermal patch (F3). Conclusion: The present study showed that the prepared economic lornoxicam transdermal patch has good properties with high efficiency as an anti-inflammatory drug on acute and chronic inflammatory models.

INTRODUCTION: Inflammation is a reaction of tissue to injury, expressed by five cardinal points: pain, swelling, redness, heat, and loss of function. None steroidal anti-inflammatory drugs (NSAIDs) have analgesic, antipyretic, and anti-inflammatory effects. Lornoxicam (LX) is a new NSAID belonging to the oxicam class. As with other NSAIDs, the principle mechanism of action of LX relates to the inhibition of cyclooxygenase (COX), the key enzyme of the arachidonic acid pathway.
resulting in the inhibition of prostaglandin (PG) synthesis \(^1\)\(^-\)\(^3\). It differs from other oxicam compounds in its potent inhibition of (PGs) biosynthesis a property that explains the pronounced efficacy of the drug. (PGs) are involved in all phases of inflammatory events including fever, pain reaction, and physiological functions like intestinal motility, vascular tone, and gastric acid secretion \(^4\). LX is distinguished from established oxicams by its short plasma half-life (3-5h) and good gastrointestinal tolerability \(^5\)\(^-\)\(^6\).

Thus, in rat polymorphonuclear leukocytes, LX potently inhibited the formation of PGD\(_2\) \(^7\). \textit{In-vivo} LX exhibited anti-inflammatory activities in acute (carrageenan-induced paw edema) as well as in chronic inflammation (adjuvant-induced arthritis) that were more potently than the ones of other oxicams \(^8\). Clinical investigations have established LX as a potent analgesic with excellent anti-inflammatory properties in a range of painful or inflammatory conditions, including postoperative pain and rheumatoid arthritis (RA) \(^7\)\(^-\)\(^8\). LX had protective effects on myocardial infarction in rats under ischemia and ischemia-reperfusion \(^9\).

An experimental study in mice has demonstrated its protective effects against herpetic stromal keratitis (HSK) through down-regulation of nuclear factor Kappa B (NF-Kappa B) activation \(^10\). It is effectively relieved the symptoms of osteoarthritis, and ankylosing spondylitis \(^11\)\(^-\)\(^13\). LX had shown strong analgesic effects after dental surgery, hysterectomy, Lumbar disk surgery and in controlling lower back pain \(^14\)\(^-\)\(^16\). In a series of studies LX was administered intraperitoneally, intravenously, intramuscularly and this play a role in the mechanism of systemic absorption and incidence of adverse effects \(^17\). Studies the effect of the drug by the topical application are not enough studies. Thus, the purpose of this study is to develop economic LX transdermal patch and to investigate LX effects as an anti-inflammatory for the treatment of inflammation in the rat model in acute and chronic models.

**MATERIALS AND METHODS:**

**Materials:** Lornoxicam (LX) was kindly donated by Delta Pharmaceuticals company, Cairo, Egypt; Eudragit\(^\circledR\) RS-100 and RL-100 were a gift from Evonic, Darmstadt, Germany; Diethyl phthalate (Lobochemie Pvt. Ltd, India), methyl alcohol, ethyl alcohol, calcium chloride, sodium chloride, sodium hydrogen phosphate and potassium dihydrogen phosphate of analytical grade were purchased from Adwic pharmaceutical company, Egypt. Carrageenan was purchased from Sigma-Aldrich Chemicals Co., ST Louis USA.

**Methods:**

**Preparation of Lornoxicam (LX) transdermal patches:** LX transdermal patches contained 16mg lornoxicam were prepared using Eudragit\(^\circledR\) RL-100 and RS-100 in three different ratios: 1:2 (F1), 1:1 (F2) and 2:1 (F3) respectively. Diethyl phthalate was used as a plasticizer in the concentration of 20% w/w. The transdermal patches were prepared by solvent evaporation casting technique as follows: Eudragit polymers, drug, and plasticizer were dissolved in methanol. The alcoholic solution was mixed in a beaker and stirred with a magnetic stirrer to accomplish a homogeneous mixture, and the resulting solution was poured in a plastic container of diameter 2 cm. The solvent was allowed to evaporate at ambient conditions, and the obtained transdermal patches were stored in a desiccator over calcium chloride (CaCl\(_2\)) and evaluated within one week \(^18\).

**Evaluation of Lornoxicam Transdermal Patches:**

1. **Drug Content of the Patch:** A 2cm\(^2\) patch was cut into small pieces, put into a 100 ml phosphate buffered saline PBS (pH 7.4), and shaken in a mechanical shaker at 37 \(^\circ\)C and 100 rpm for 24 h. Then the whole solution was ultrasonicated for 15 min. After filtration, the drug was estimated spectrophotometrically (UV-VS-Spectrophotometer, multicell changer, 6705-Jenway, Bibby scientific. Ltd, UK) at a wavelength of 376 nm and the concentration was deduced in accordance to a pre-constructed calibration curve in PBS (pH 7.4). The experiment was repeated three times, and the mean drug content for each formulation was determined \(^18\).

2. **LX Patch Thickness:** The thickness of the patches was determined by measuring the thickness at the 4 edges and the center of the formulated films using a micrometer screw
gauge\textsuperscript{19} (Mitutoyo Corp, Japan) and the results were expressed as average thickness ± SD.

3. Differential Scanning Calorimetry (DSC): Samples of the drug, pure patch components and the physical mixture of the drug and the polymers were analyzed by DSC using a Shimadzu DSC-60 (Shimadzu, Kyoto, Japan).

4. Folding Endurance of LX Patches: The mechanical properties of the transdermal patches were determined. Three patches of each formulation of size 2 × 2 cm were cut by using a sharp blade. Folding endurance of the buccal films was determined by repeatedly folding patch at the same place till it broke. The mean value was calculated\textsuperscript{19,20}.

5. Determination of LX Patch Surface pH: Drug patch was left to swell for 30 min on the surface of 2% w/v agar plate. The surface pH was measured using pH paper (Whatman, USA) placed on the surface of the swollen patch\textsuperscript{21}.

6. In-vitro Drug Permeation from the Patch: The drug permeated from different transdermal patches through synthetic cellulose acetate membrane was studied. USP dissolution tester (BLHMO15K-10, Oriental Motor, Japan) of basket type with slight modification was utilized. Glass cylinders of 10 cm length and 2.5 cm diameter were used instead of the regular baskets. Cellulose acetate membrane with a 12,000-14,000 molecular weight cut off was soaked in saline PBS (pH 7.4) overnight before the study. Drug patch was placed under the presoaked cellulose membrane, were wrapped on one end of the glass cylinders and were fitted on the basket shaft from the other end. The glass cylinders were placed in the vessels of the dissolution tester so that the membrane and film were only touching the surface of 100 ml of saline PBS (pH 7.4) at 37 °C and stirred at a constant speed of 50 rpm\textsuperscript{19}. At predetermined time intervals 0.5, 1, 1.5, 2, 4, 8, 10 and 24 h, 5 ml aliquots of the release medium were withdrawn for analysis and replaced with an equal volume of fresh buffered solution to maintain a constant volume. The absorbencies of the collected and filtered samples were measured spectrophotometrically at 376 nm. Each patch was evaluated three times, and the results were expressed as the mean value of three experiments ± SD.

Animals and Experimental Design: This study was conducted on eighty adult albino rats weighing 180-200gm. They bred in the animal house of Kasr El Aini, Faculty of Medicine, Cairo University. They were caged in a fully ventilated room, exposed to natural daily light/dark cycle. They were allowed food and water \textit{ad libitum}. The animals were handled according to the guidelines of Helsinki declaration rights (1975) of using laboratory animals.

1. For Acute Experimental (Rat Paw Edema): Animals were divided into 5 groups each of 8 animals. Carrageenan-induced rat paw edema in all groups for the present study according to the method described by Winter\textsuperscript{22} and El Nabarawi \textit{et al.}\textsuperscript{23}. Suspension of 1% carrageenan is prepared freshly in normal saline and injected into the subplantar region of the right hind paw in a dose of 0.1 ml. The intensity of edema was assessed by measuring the paw volume (ml) by plethysmometer (7410 Ugo Basile, Italy) after 1 h and 5 h. The edema and inhibition rate percentage of each group was calculated as follows:

\begin{equation}
\text{Edema rate (E \%)} = \frac{V_t - V_0 \times 100}{V_0}
\end{equation}

\begin{equation}
\text{Inhibition rate = } \frac{E_c - E_t \times 100}{E_t}
\end{equation}

Where $V_0$ is the mean paw volume before carrageenan injection (ml), $V_t$ is the mean paw volume after carrageenan injection (ml), Ec is the edema rate of the control group, and Et is the edema rate of the treated group\textsuperscript{24}.

Group I received no treatment, Group II rats received LX 5mg/kg parenterally SC (behind the neck) one hour before induction of inflammation. Group III, Group IV, and Group V were subjected to the application of LX patch (F1), (F2), (F3) respectively.
RESULTS AND DISCUSSION: A transdermal patches of lornoxicam were prepared with Eudragit RL 100: Eudragit RS 100 in three different ratios with diethyl phthalate as plasticizer using the solvent evaporation technique. Results showed that the drug content of the patches was ranged from 96.45 to 103.33%. The patches thickness was ranged from 0.36 to 0.46 mm. Results obtained showed that films prepared were a uniform thickness. The difference in thickness was due to the concentration of polymer in each device. The pH of the LX patch was found to be 6.5.

Fig. 1 showed the thermograms of pure drug and the physical mixture of the drug and the polymers (Eudragit® RL-100, Eudragit® RS-100) in ratio 1:1. The superimposition of the thermograms of the physical mixture, prepared by simple blending of drug and polymer, to those of the patch components indicated the absence of interactions between the drug and the polymers.

The obtained data revealed that when increasing the ratio of the Eudragit® RL-100 polymer (F3), there was a corresponding increase in the folding endurance of patches. Diethyl phthalate 20% in the Eudragit® patches led to increasing elasticity for the patches. The order of increasing folding endurance of patches was in order: F3 > F2 > F1. These results were in a good agreement of Entwistle C and Rowe R 27.

They found that DEP in the Eudragit® film increase in elongation and correspond in a decrease in tensile strength. This was because plasticizers acted by inserting themselves between the polymer strands, breaking the polymer-polymer bond, which led to an increase in the molecular mobility of the polymer strand 27.

Thus, it was expected that as the concentration of the plasticizer increased, the degree of the film stiffness decreased, whereas the film ductility increased. Upon addition of plasticizer, flexibilities of polymer macromolecules or macromolecular segments increase as a result of the loosening of tightness of intermolecular forces 28. It was also found that weakening of interaction of the polymer chains led to a decrease in the tensile strength and an increase in the percent elongation of the films 29.

FIG. 2: PERMEATION OF LORNOXICAM FROM DIFFERENT PATCHES THROUGH CELLULOSE ACETATE MEMBRANE

Table 1 and Fig. 3 showed the effect of LX in different formulae tested for in-vitro permeation in rat paw edema after 1 and 5 h. The swelling is markedly increased in group I then after injection by LX the marked inhibition showed in group II after 1 h. The degree of swelling was significantly decreased by F3 followed by F2 followed by F1 after one and five hours.

The degree of inhibition was significantly increased by F3, followed by F2 followed by F1 after five hours. These results were in a good agreement with in vitro drug permeation from different patches through cellulose acetate membrane.

Table 2 showed the maximum edema was shown group I. Edema was significantly decreased in group V followed by group IV followed by group III and then group II. These results demonstrated that the maximum inhibition of edema was by patch F3 and not by injection as in the acute study.

Our results are by 31, 32 which stated that LX is approved for intravenous, intramuscular, and oral use, no toxicological data are available regarding its intra-articular administration. The peripheral effects of NSAIDs are peripheral, and therefore, local application to the site of injury should produce analgesia while minimizing systemic side effects.
In the arachidonic acid pathway.

While COX 1 is thought to account for homeostatic amounts of eicosanoids, COX2 is induced during inflammation leading to the formation of pathologic amounts of prostaglandins (PGS). The inhibition of (PGS) synthesis by NSAIDs has been demonstrated to reduce inflammatory symptoms such as edema and pain.

Other mediators of inflammation such as reactive oxygen products and cytokines which contribute to inflammation and pain, leading to transcriptional induction of COX-2 gene, the expression of the gene encoding inducible nitric oxide synthase (iNos) is induced, leading to increase level of nitric oxide in inflammation tissue which leads to edema formation and pain.

LX was found to be the most potent balanced inhibitor of human COX 1, 2. The in-vitro activities described supporting the marked anti-inflammatory and analgesic activities of LX found in animal models as well as in clinical studies.

LX is at least 10 times more potent as an anti-inflammatory agent than piroxicam and was also tenfold more active than tenoxicam in inhibiting carrageenan-induced edema in the rat paw swelling in the adjuvant-induced polyarthritis rat.

The volume of exudates obtained was significantly decreased by F3 followed by F2 followed by F1 after 7 days of treatment. These results were in a good agreement with in-vitro drug permeation from different patches through cellulose acetate membrane. The order of decreasing volume of exudates was as follows: F3 > F2 > F1 > injection.

The potent nonselective COX inhibition by LX was observed in vitro is in good agreement with animal experiments where inhibition of COX 1 mediated PGS synthesis is thought to be involved in compound efficacy such as acetylcholine-induced writhing or where COX 2 inhibition such as carrageenan-induced paw edema has been suggested to be causal for anti-inflammatory effects.

Furthermore, LX was potently effective as anti-inflammatory and analgesic activity. Moreover, several studies have examined the role of nonselective COX inhibitors both in animal models and in patients demonstrated beneficial effects of NSAIDs on the TNF-α level which can be ameliorated.

LX has also shown marked inhibitory activity on endotoxin-induced IL6 formation in THP1 monocytes with less activity on TNF-α and IL-1. LX treatment suppressed both NF-Kappa B activation and TNF-α expression in biological analysis.

In addition, Pruss et al. stated that the powerful inhibition of cyclo-oxygenase had manifested itself as a highly potent analgesic and anti-inflammatory effects in animal studies. Studies have demonstrated that LX inhibits polymorphonuclear (PMN) leukocyte migration, inhibits the release of superoxide from human PMN-leukocytes, inhibits the release of platelet-derived growth factor (PDGF) from human platelets and stimulates the synthesis of proteoglycans in cartilage in tissue culture.

The volume of exudates obtained was significantly decreased by F3 followed by F2 followed by F1 after 7 days treatment. These results were in a good agreement with in-vitro drug permeation from different patches through cellulose acetate membrane. The order of decreasing volume of exudates was as follows: F3 > F2 > F1 > injection.
CONCLUSION: The present study showed that lornoxicam transdermal patches proved to be economic in the manufacture, non-irritant, and had anti-inflammatory effects on acute and chronic models of inflammation using albino rats. Also, topical application of LX transdermal patch reduces side effects of the drug which induced by other routes. Furthermore, F3 patch possesses superior to injection route in the treatment of edema in chronic models.
