PREPARATION AND EVALUATION OF ANTIMICROBIAL HERBAL FORMULATION OF *PTEROSPERMUM ACERIFOLIUM* WILLD

Ashis Kumar Manna*, Upendranath Nanda and Subrat Kar

Seemanta Institute of Pharmaceutical Sciences, Jharpokharia, Mayurbhanj - 757086, Odisha, India.

ABSTRACT: The present work deals with formulation of topical gels containing aqueous extract of *P. acerifolium* seeds and also to evaluate the prepared gels against some Gram-positive and Gram-negative bacteria. The antibacterial activity of various *P. acerifolium* seed extracts was measured through determining minimum inhibitory concentration (MIC) by cube dilution method and zone of inhibition by disc diffusion method against *E. coli*, *P. aeruginosa* and *S. aureus*. Aqueous *P. acerifolium* seed extracts exhibited comparatively higher antibacterial potential in comparison with that of other extracts and employed to formulate topical herbal gels using 4.5 % sodium carboxymethyl cellulose as gel base. Prepared herbal gels were tested for pH, viscosity, extrudability and spreadability. All the prepared gels were subjected to antibacterial study by determining zone of inhibition by disc diffusion method. Herbal gels containing 15 % aqueous *P. acerifolium* seed extract exhibited better zones of inhibition against *E. coli*, *P. aeruginosa* and *S. aureus* in comparison with that of 5 % and 10 %. From the results of this study, it can be concluded that herbal gels containing 15 % aqueous *P. acerifolium* seed extract is found suitable for topical use against bacterial infections.

INTRODUCTION: In recent years, considerable research efforts have been directed towards the use of naturally derived materials in various medicinal, biomedical as well as pharmaceutical applications. Amongst these naturally derived materials, herbal medicines have been recognized as the most important remedy in the traditional medicine system all over the world by the people to treat various diseases since antiquity. According to World Health Organization (WHO 1993), a major fraction (almost 80 %) of the global population is dependent on the traditional medicine systems with the use of extracts derived from plant parts like leaves, pods, bark, fruits, seed, roots, exudates, etc. Moreover, these herbal medicines are cheap, safe and devoid of side effects on long term use. Extensive survey of the ethnomedicinal and phytochemical literature reveals that numerous herbal extracts have already been studied for their anti-microbial activities against many microbial infections.

*Pterospermum acerifolium* willd (family, Sterculiaceae, commonly known as ‘Kanak champa’) is a shrub distributed in tropical Asia.
It is a popular ornamental plant having wide range of medicinal properties. Various part of *P. acerifolium* plant is used for the treatment of different diseases like conjunctivitis, anorexia, dysmenorrhoea and fever. *P. acerifolium* is also reported as bitter, acidic, anti-inflammatory, analgesic, sedative, carminative, digestive, antimicrobial, anthelmintic. Extensive survey of literature reveals the fact that very little work has been done in the direction of its use as antibacterial through topical gels. No topical gel formulation yet is prepared using this herbal drug towards the antibacterial dermatological treatment. Therefore, in the present work, attempt has been taken to develop topical gels containing aqueous extract of *P. acerifolium* seeds and also to evaluate the prepared gels against some Gram-positive and Gram-negative bacteria.

**MATERIALS AND METHODS:**

**Collection and authentication of plant material:** Seeds of *P. acerifolium* were collected in the month of January, 2009, from the hill area near the bank of Subarnarekha River in the district of Mayurbhanj, Odisha. The collected plant with complete herbarium was authenticated at Botanical survey of India, Central National Herbarium, Botanical Garden, Howrah, Kolkata (vide Letter No. CNH/1-1(15)/2009/Tech 11/413). Also a sample specimen was deposited there.

**Preparation of Extract:** 1 kg of the air dried seeds of *P. acerifolium* was reduced to fine powder and extracted using Soxhelet apparatus with petroleum ether, ethanol and purified water up to 30 siphons each one after another. Each extract was concentrated using a Rota evaporator. The marc left after extraction was dried in an air oven below 30°C.

**Microorganism:** The microorganisms were obtained from the microbiological laboratory of Dept. of Pharmaceutical Technology, Jadavpur University, Kolkata. The details about the microorganism are shown in Table 1.

**Antimicrobial Screening:** Determination of Minimum Inhibitory Concentration (MIC).

MIC of each extract was determined by cube dilution method. 10 Test tubes for each extract per microorganism were thoroughly washed and sterilized. 0.5 ml of test solutions (7.8 µg/ml to 1000 µg/ml) was taken in 8 test tubes. 0.5 ml of freshly prepared and sterilized nutrient broth & 0.5 ml 6 % DMSO was added to each of 8 test tubes. Test tubes were thoroughly shaken. To each test tube, 50 µg of 24 hours sub culture of bacteria was added and shaken properly. The 9th test tube contained 0.5 ml of nutrient broth & 0.5 ml 6 % DMSO and 50 µg of sub culture of bacteria to act as positive control and 10th test tube contained 0.5 ml of nutrient broth & 1 ml of 6 % DMSO to act as negative control. All the test tubes were incubated in an incubator (Remi Corporation, India) at 37°C for 24 hours and observed for turbidity comparing with both the controls. Same procedure was adopted for all extracts and all the three bacteria.

**Determination of Zone of Inhibition:** Zone of inhibition was determined for each extract at a concentration of 1000 µg/ml and compare to that of standard ciprofloxacin 5 µg/disc by disc diffusion method. Agar plates were made by pouring nutrient agar suspension (sterilized) in cleaned petridish to get 4 mm thickness (approx). Plates were kept under laminar air flow.

Stock solution of each extract 100 mg/ml were prepared by dissolving the extract in 6 % DMSO, paper disc (Whatman® No. 1) of 6 mm diameter were cut and sterilized in hot air oven. 10 µl (1000 µg/disc) of each extract was taken in a sterile pipette and soaked in paper disc. The disc was dried. The discs were carefully kept on the agar media and slightly pressed for proper fixing. Standard disc of ciprofloxacin (5 µg/disc) was taken and placed on the media and fixed properly. The plates were incubated at 37°C for 24 hours. Plates were observed for zone of inhibition.
**Formulation and Preparation of Herbal Gels:** Accurately weighed quantity of Sodium Carboxymethyl Cellulose was soaked in distilled water and was allowed to swell. Accurate quantity of aqueous extract was weighed and dispersed in distilled water. The drug dispersion was added to the soaked polymer with stirring, until a gel was formed. The prepared gel was filled in collapsible tube and sealed by crimping the ends. Different formulations for the herbal gels by using sodium carboxymethyl cellulose are given in **Table 2**.

**Evaluation of Herbal Gels:**

**pH measurements:** The pH of the gels was measured by using digital pH meter (Systronics Instruments, India). The glass electrode was completely dipped into the gel system so as to cover the electrode and the pHs of gels were measured within 5 min.

**Determination of Viscosity:** The viscosity of formulated gels was determined using Brookfield viscometer (DV-III Units Programmable Rheometer, USA) using the spindle No. 4 at 1.5 rpm.

**Determination of extrudability:** It is a useful empirical test to measure the force required to extrude the material from a bottle or tube since the passing of gels have gained a considerable importance in the delivery of desired quantity of gel from collapsible tubes. Therefore, the measurement of extrudability becomes an important criterion for gels. While not strictly a test of product characteristics due to inclusion of force necessary to deform the whitener the method applied is for the determination of applied shear in the region of the rheogram corresponding to the shear rate exceeding. The yield value was exhibiting. Consequent plug flow on such apparatus is described by Wood et al., 35. The gels were filled in standard capped collapsible tubes and sealed by crimping the ends. The weight of tube was recorded. The tube was placed between two glass slides and was clamped. A 500 gm weight was placed over the glass slide and then the cap was removed. The amount of gel extruded was collected and weighted.

**Determination of Spreadability:** Two glass slides 6 cm long were used containing gel in between. Lower slide was fixed on a wooden plate and the upper one was tied to a hook having a balance at the other end in which a weight was kept in order to pull that slide. Five gram of gel was uniformly placed on the lower slide and the upper slide was placed on it. A one kilogram weight was kept on the slides for five minutes to expel the entrapped air. The excess discharged gel was carefully scrapped off. A weight of 80 gm. was kept on the balance. The time in seconds required to separate the slides completely was noted. Less time indicates more slip and better spreadability. The experiments were repeated thrice and mean value was taken.

Spreadability is calculated using the formula:

\[
S = M \times \frac{L}{t}
\]

where, S = Spreadability of gel; M = weight tied to the upper slide; L = length of glass slide; t = time taken.

**RESULTS AND DISCUSSION:** Topical gels are semisolid formulations, which have gained a greater deal of importance in the medical field for their topical effect in the treatment of pain, strain, inflammation, infections and other diseases 36 - 40. In the current work, topical herbal gels containing aqueous extract of *P. acerifolium* seeds was developed using sodium carboxymethyl cellulose. The antibacterial potential of these formulated herbal gels were also investigated against *Escherichia coli*, *Pseudomonas aeruginosa* and *Staphylococcus aureus*. MIC of *P. acerifolium* seed extracts was determined by cube dilution method. It was observed that all the seed extracts showed MIC ranging from 31.25 to 1000 μg/ml (**Table 3**). The aqueous extract showed lowest MIC value against
all three bacteria. The aqueous extract was found to possess MIC value of 31.25 μg/ml, against *E. coli* and *S. aureus*. Against *P. aeruginosa*, it was 125 μg/ml. From the above observation, it was clearly concluded that aqueous extract of seeds showed lowest MIC value.

In order to evaluate the antibacterial activity of extracts having MIC up to 1000 μg/ml, disc diffusion method was adopted and zone of inhibition was recorded. The antibacterial sensitivity of extracts and that of standard (ciprofloxacin) were compared. Aqueous extract of *P. acerifolium* seeds at 1000 μg/disc showed higher zone of inhibition against *P. aeruginosa* (22 mm) than that of *S. aureus* and *E. Coli* (17 mm) while comparing to ciprofloxacin (standard, 5 μg/disc) (32 – 36 mm). Other extracts showed less zone of inhibitions. Thus, antibacterial screening of *P. acerifolium* seed extracts by disc diffusion method finally showed comparatively higher antibacterial potential in case of aqueous extract of seeds and hence, it was taken for further formulation study.

Prepared herbal gels of aqueous *P. acerifolium* seed extract prepared using 4.5% sodium carboxymethyl cellulose were tested for pH, viscosity, extrudability and spreadability. pHs of these gels were within the range between, 6.28 – 7.30. Viscosities of these herbal gels were measured within 42000 – 52000 cps. It was observed that gel containing 15 % aqueous *P. acerifolium* seed extract showed good extrudability in comparison with other formulated gels. The spreadability of these gels was found almost similar. From these results, it can be suggested that the gel containing 15% aqueous extract exhibited satisfactory extrudability and spreadability. The extrusion of gels from the collapsible tube is important during application; whereas, spreadability plays an important role in helping of uniform application of gels. A good gel takes less time to spread and should have high spreadability.

All the prepared gels were subjected to antibacterial study by determining zones of inhibition disc diffusion method. Zone of inhibitions against *E. coli*, *P. aeruginosa* and *S. aureus* were compared with the standard gels containing clarithromycin (1%). Clarithromycin gel (1%) exhibited zones of inhibition in the range of 28 – 37 mm for all these 3 bacteria. It was observed that herbal gel containing 15 % aqueous *P. acerifolium* seed extract exhibited better zones of inhibition against *E. coli*, *P. aeruginosa* and *S. aureus* in comparison with that of 5 % and 10 %.

---

*International Journal of Pharmaceutical Sciences and Research* 5311
Zones of inhibitions of herbal gel containing 15 % aqueous *P. acerifolium* seed extract against *E. coli*, *P. aeruginosa* and *S. aureus* is shown in Fig. 1. The antibacterial potential of these herbal gels were found to be increased with the increasing percentage content of the aqueous *P. acerifolium* seed extract present in herbal gels.

**FIG. 1: ZONES OF INHIBITIONS OF HERBAL GEL CONTAINING 15 % AQUEOUS *P. ACERIFOLIUM* SEED EXTRACT AGAINST (A) *E. COLI*, (B) *P. AERUGINOSA* AND (C) *S. AUREUS***

**CONCLUSION:** Extracts from *P. acerifolium* seeds were tested for antibacterial activity against some Gram-positive and Gram-negative bacteria like *E. coli*, *P. aeruginosa* and *S. aureus*. MIC (by cube dilution method) and zone of inhibition (by disc diffusion method) of aqueous *P. acerifolium* seed extracts exhibited comparatively higher antibacterial potential in comparison with that of other extracts. On the basis of it, topical herbal gels containing aqueous extract of *P. acerifolium* seeds were formulated using 4.5 % sodium carboxymethyl cellulose as gel base and evaluated for their antibacterial potential against *E. coli*, *P. aeruginosa* and *S. aureus*. pHs and viscosities of...
these gels were within the range, 6.28 – 7.30 and 42000 – 52000 cps, respectively. Gel containing 15% aqueous extract exhibited satisfactory extrudability and spreadability. All the prepared gels were subjected to antibacterial study by determining zones of inhibition disc diffusion method. Herbal gels containing 15% aqueous *P. acerifolium* seed extract exhibited better zones of inhibition against *E. coli*, *P. aeruginosa* and *S. aureus* in comparison with that of 5% and 10%. From the results of this study, it can be concluded that herbal gels containing 15% aqueous *P. acerifolium* seed extract was found suitable for topical use against bacterial infections. It can be suggested that before its commercialization, the gel formulations should be subjected to detailed clinical studies using animals as well as human subjects. Also, extensive accelerated stability studies should be examined.

ACKNOWLEDGEMENT: We are very grateful to BPUT, Rourkela, Governing body SIPS for providing facilities and thankful to Dr. Sammoy Karmakar, Prof. Jadavepur University, Kolkata and Dr. Amit Kumar Nayak, Asso Prof., SIPS, Jharpokharia for their suggestions.
